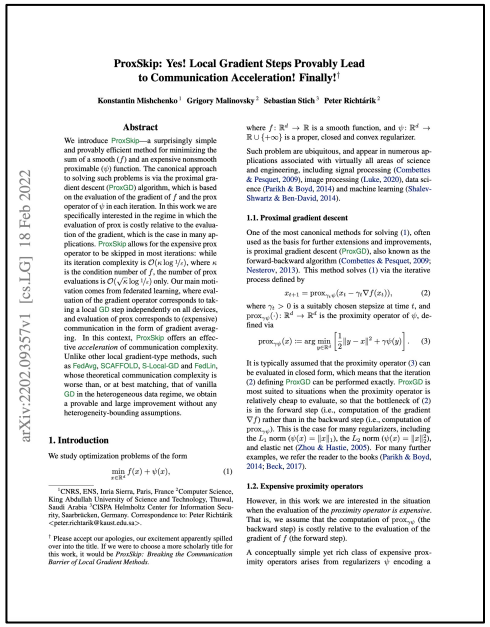
ProxSkip: Yes! Local Gradient Steps Provably Lead to Communication Acceleration! Finally!



ProxSkip: Yes! Local Gradient Steps Provably Lead to Communication Acceleration! Finally!†

Konstantin Mishchenko[1] Grigory Malinovsky[2] Sebastian Stich[3] Peter Richtárik[2]

Abstract

We introduce ProxSkip—a surprisingly simple and provably efficient method for minimizing the sum of a smooth (f) and an expensive nonsmooth proximable (ψ) function. The canonical approach to solving such problems is via the proximal gradient descent (ProxGD) algorithm, which is based on the evaluation of the gradient of f and the prox operator of ψ in each iteration. In this work we are specifically interested in the regime in which the evaluation of prox is costly relative to the evaluation of the gradient, which is the case in many applications. ProxSkip allows for the expensive prox operator to be skipped in most iterations: while its iteration complexity is $\mathcal{O}(\kappa \log \frac{1}{\varepsilon})$, where κ is the condition number of f, the number of prox evaluations is $\mathcal{O}(\sqrt{\kappa} \log \frac{1}{\varepsilon})$ only. Our main motivation comes from federated learning, where evaluation of the gradient operator corresponds to taking a local GD step independently on all devices, and evaluation of prox corresponds to (expensive) communication in the form of gradient averaging. In this context, ProxSkip offers an effective *acceleration* of communication complexity. Unlike other local gradient-type methods, such as FedAvg, SCAFFOLD, S-Local-GD and FedLin, whose theoretical communication complexity is worse than, or at best matching, that of vanilla GD in the heterogeneous data regime, we obtain a provable and large improvement without any heterogeneity-bounding assumptions.

1. Introduction

We study optimization problems of the form

$$\min_{x \in \mathbb{R}^d} f(x) + \psi(x), \qquad (1)$$

where $f : \mathbb{R}^d \to \mathbb{R}$ is a smooth function, and $\psi : \mathbb{R}^d \to \mathbb{R} \cup \{+\infty\}$ is a proper, closed and convex regularizer.

Such problem are ubiquitous, and appear in numerous applications associated with virtually all areas of science and engineering, including signal processing (Combettes & Pesquet, 2009), image processing (Luke, 2020), data science (Parikh & Boyd, 2014) and machine learning (Shalev-Shwartz & Ben-David, 2014).

1.1. Proximal gradient descent

One of the most canonical methods for solving (1), often used as the basis for further extensions and improvements, is proximal gradient descent (ProxGD), also known as the forward-backward algorithm (Combettes & Pesquet, 2009; Nesterov, 2013). This method solves (1) via the iterative process defined by

$$x_{t+1} = \text{prox}_{\gamma\psi}(x_t - \gamma \nabla f(x_t)), \qquad (2)$$

where $\gamma > 0$ is a suitably chosen stepsize at time t, and $\text{prox}_{\gamma\psi}(\cdot) : \mathbb{R}^d \to \mathbb{R}^d$ is the proximity operator of ψ, defined via

$$\text{prox}_{\gamma\psi}(x) := \arg\min_{y \in \mathbb{R}^d} \left[\frac{1}{2}\|y - x\|^2 + \gamma\psi(y) \right]. \qquad (3)$$

It is typically assumed that the proximity operator (3) can be evaluated in closed form, which means that the iteration (2) defining ProxGD can be performed exactly. ProxGD is most suited to situations when the proximity operator is relatively cheap to evaluate, so that the bottleneck of (2) is in the forward step (i.e., computation of the gradient ∇f) rather than in the backward step (i.e., computation of $\text{prox}_{\gamma\psi}$). This is the case for many regularizers, including the L_1 norm ($\psi(x) = \|x\|_1$), the L_2 norm ($\psi(x) = \|x\|_2^2$), and elastic net (Zhou & Hastie, 2005). For many further examples, we refer the reader to the books (Parikh & Boyd, 2014; Beck, 2017).

1.2. Expensive proximity operators

However, in this work we are interested in the situation when the evaluation of the *proximity operator is expensive*. That is, we assume that the computation of $\text{prox}_{\gamma\psi}$ (the backward step) is costly relative to the evaluation of the gradient of f (the forward step).

A conceptually simple yet rich class of expensive proximity operators arises from regularizers ψ encoding a

Part 1
Introduction

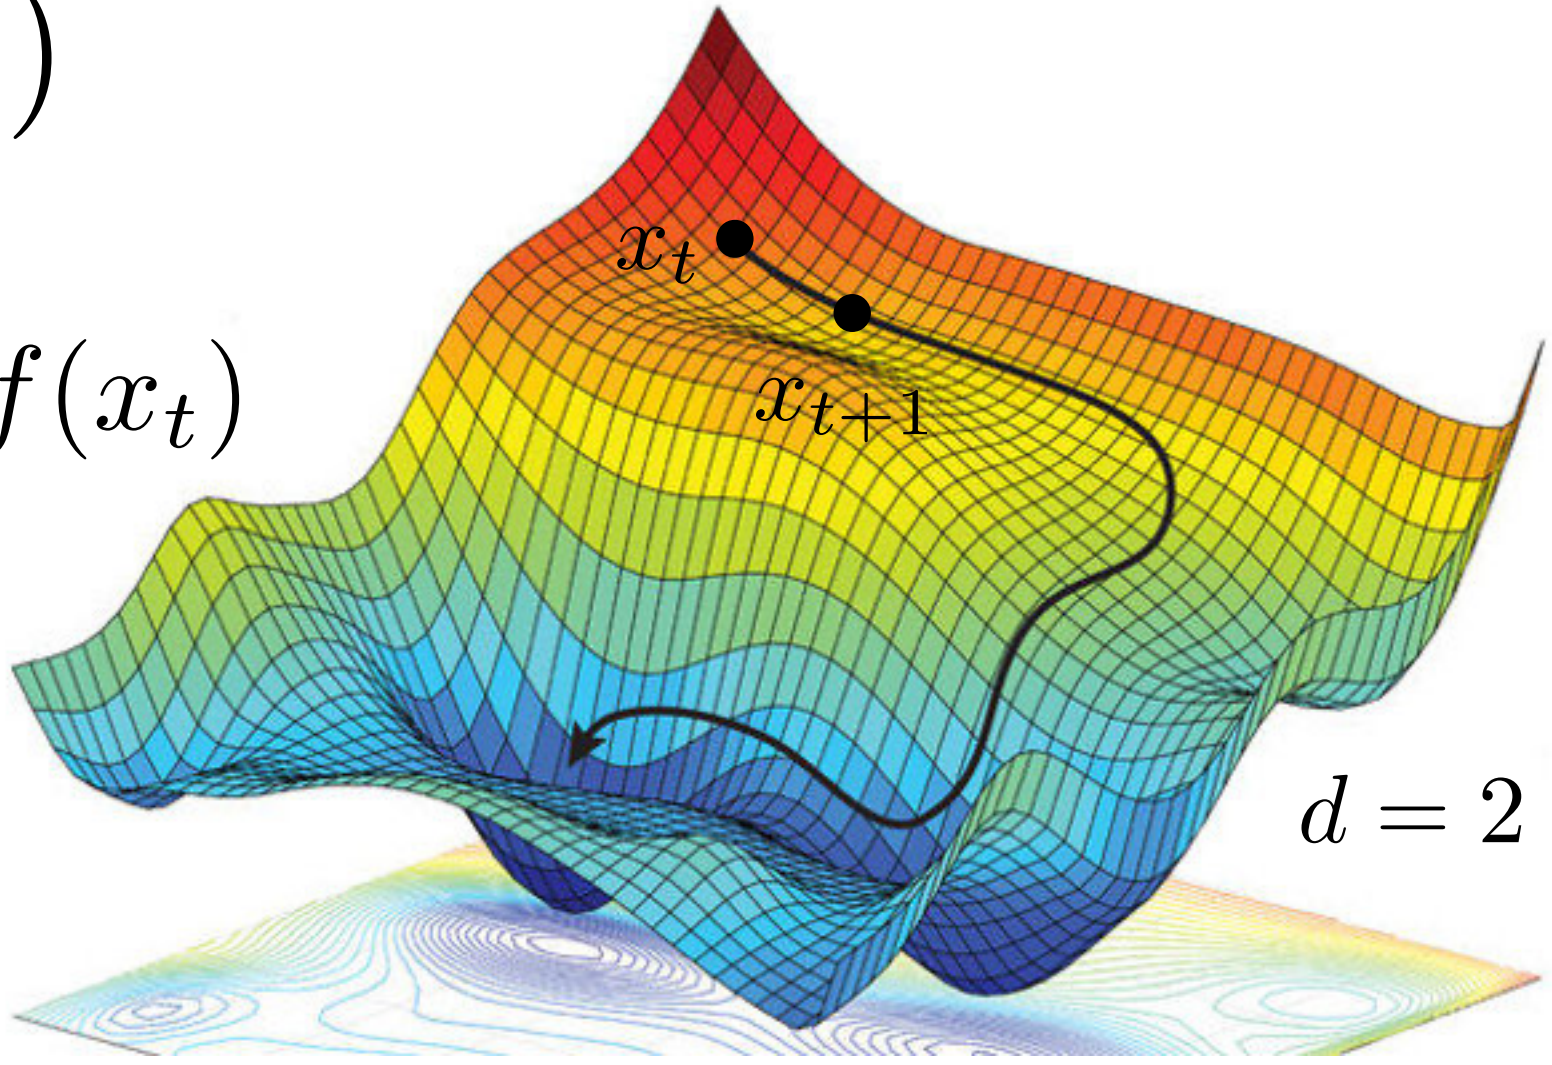
Gradient Descent

Gradient Descent

$$\min_{x \in \mathbb{R}^d} f(x)$$

$$x_{t+1} = x_t - \gamma \nabla f(x_t)$$

Stepsize / Learning rate



Distributed Gradient Descent

Federated Training of a Supervised Machine Learning Model

$$\min_{x \in \mathbb{R}^d} f(x) \stackrel{\text{def}}{=} \frac{1}{n} \sum_{i=1}^{n} f_i(x)$$

devices / machines

model parameters / features

Loss on local data $\mathcal{D}_i$ stored on device i

$$f_i(x) = \mathbb{E}_{\xi \sim \mathcal{D}_i} f_{i,\xi}(x)$$

The datasets $\mathcal{D}_1, \ldots, \mathcal{D}_n$ can be arbitrarily heterogeneous

Distributed Gradient Descent

Optimization problem:

$$\min_{x\in\mathbb{R}^d} f(x) \stackrel{\text{def}}{=} \frac{1}{n}\sum_{i=1}^{n} f_i(x)$$

$$\begin{aligned} x_{t+1} &= x_t - \gamma \nabla f(x_t) \\ &= x_t - \gamma \frac{1}{n}\sum_{i=1}^{n} \nabla f_i(x_t) \end{aligned}$$

$$f(x) = \frac{1}{n}\sum_{i=1}^{n} f_i(x_t)$$

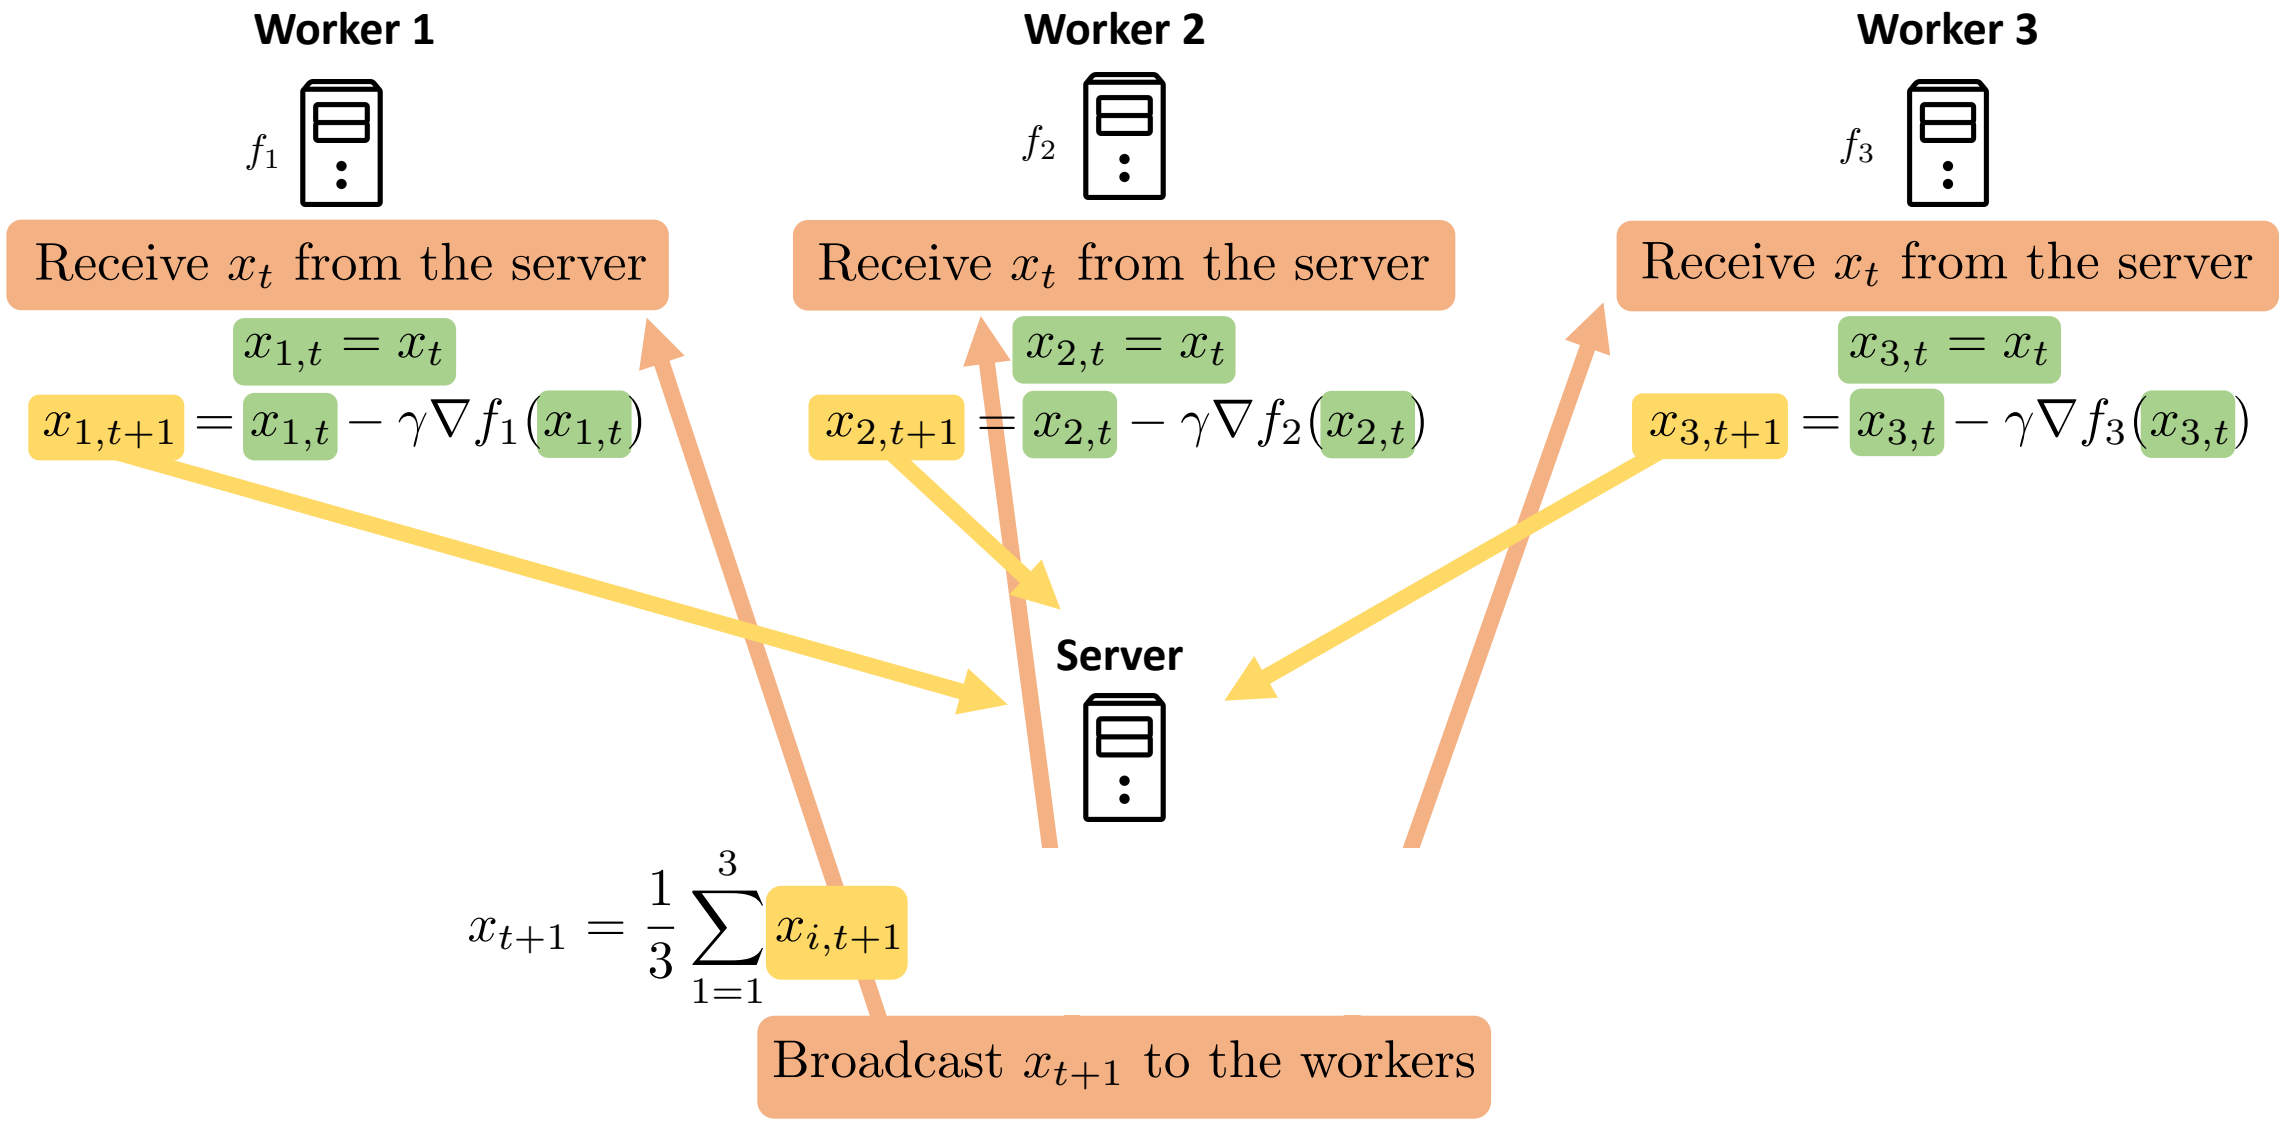
d-dimensional gradient computed by machine *i*

Distributed Gradient Descent

(Each worker performs 1 GD step using its local function, and the results are averaged)

Optimization problem:

$$\min_{x\in\mathbb{R}^d} f(x) \stackrel{\text{def}}{=} \frac{1}{n}\sum_{i=1}^{n} f_i(x)$$



Distributed Local Gradient Descent

Distributed Local Gradient Descent

(Each worker performs *K* GD steps using its local function, and the results are averaged)

Optimization problem:

$$\min_{x\in\mathbb{R}^d} f(x) \stackrel{\text{def}}{=} \frac{1}{n}\sum_{i=1}^{n} f_i(x)$$

Key Theoretical Problem in Federated Learning

Local gradient steps are of key importance in FL.

In practice, local steps improve communication efficiency. But in theory*, they do not!!!

Is the situation hopeless, or can we show that (appropriately designed) local steps help?

Federated Learning: ProxSkip vs Baselines

Table 1. The performance of federated learning methods employing multiple local gradient steps in the strongly convex regime.

method	# local steps per round	# floats sent per round	stepsize on client i	linear rate?	# rounds	rate better than GD?
GD (Nesterov, 2004)	1	d	$\frac{1}{L}$	✓	$\tilde{\mathcal{O}}(\kappa)$ [c]	✗
LocalGD (Khaled et al., 2019; 2020)	τ	d	$\frac{1}{\tau L}$	✗	$\mathcal{O}\left(\frac{G^2}{\mu n \tau \varepsilon}\right)$ [d]	✗
Scaffold (Karimireddy et al., 2020)	τ	$2d$	$\frac{1}{\tau L}$ [e]	✓	$\tilde{\mathcal{O}}(\kappa)$ [c]	✗
S-Local-GD [a] (Gorbunov et al., 2021)	τ	$d < \# < 2d$ [f]	$\frac{1}{\tau L}$	✓	$\tilde{\mathcal{O}}(\kappa)$	✗
FedLin [b] (Mitra et al., 2021)	τ_i	$2d$	$\frac{1}{\tau_i L}$	✓	$\tilde{\mathcal{O}}(\kappa)$ [c]	✗
Scaffnew [g] (this work) for any $p \in (0, 1]$	$\frac{1}{p}$ [h]	d	$\frac{1}{L}$	✓	$\tilde{\mathcal{O}}\left(p\kappa + \frac{1}{p}\right)$ [c]	✓ (for $p > \frac{1}{\kappa}$)
Scaffnew [g] (this work) for optimal $p = \frac{1}{\sqrt{\kappa}}$	$\sqrt{\kappa}$ [h]	d	$\frac{1}{L}$	✓	$\tilde{\mathcal{O}}(\sqrt{\kappa})$ [c]	✓

[a] This is a special case of S-Local-SVRG, which is a more general method presented in (Gorbunov et al., 2021). S-Local-GD arises as a special case when full gradient is computed on each client.

[b] FedLin is a variant with a fixed but different number of local steps for each client. Earlier method S-Local-GD has the same update but random loop length.

[c] The $\tilde{\mathcal{O}}$ notation hides logarithmic factors.

[d] G is the level of dissimilarity from the assumption $\frac{1}{n}\sum_{i=1}^{n} \|\nabla f_i(x)\|^2 \leq G^2 + 2LB^2\left(f(x) - f_\star\right), \forall x.$

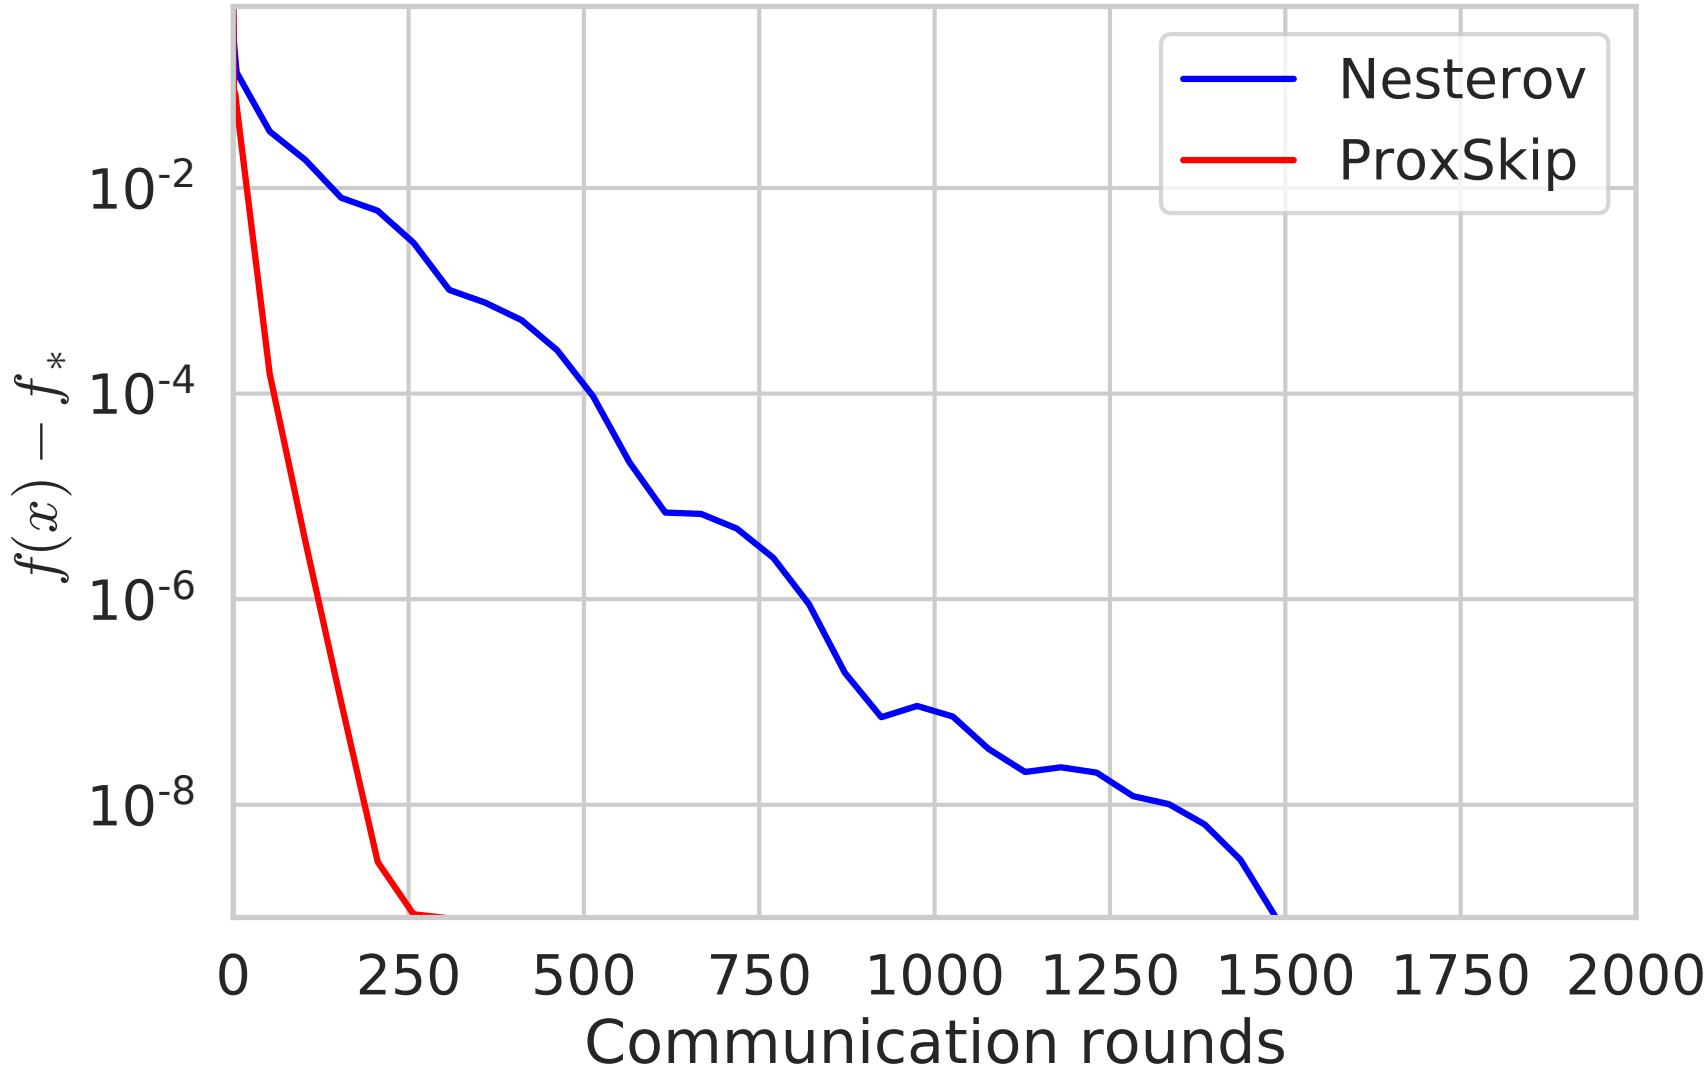
[e] We use Scaffold's cumulative local-global stepsize $\eta_l \eta_g$ for a fair comparison.

[f] The number of sent vectors depends on hyper-parameters, and it is randomized.

[g] Scaffnew (Algorithm 2) = ProxSkip (Algorithm 1) applied to the consensus formulation (6) + (7) of the finite-sum problem (5).

[h] ProxSkip (resp. Scaffnew) takes a *random* number of gradient (resp. local) steps before prox (resp. communication) is computed (resp. performed). What is shown in the table is the *expected* number of gradient (resp. local) steps.

Federated Learning: ProxSkip vs Nesterov



Part 2
Consensus Reformulation

Consensus Reformulation

Original problem:
optimization in $\mathbb{R}^d$

$$\min_{x\in\mathbb{R}^d}\left\{f(x)\stackrel{\text{def}}{=}\frac{1}{n}\sum_{i=1}^{n}f_i(x)\right\}$$

$$\Updownarrow$$

Consensus reformulation:
optimization in $\mathbb{R}^{nd}$

$$\min_{x_1,\ldots,x_n\in\mathbb{R}^d}\left\{\frac{1}{n}\sum_{i=1}^{n}f_i\left(x_i\right)+\psi\left(x_1,\ldots,x_n\right)\right\}$$

Bad: Non-differentiable function

Good: Indicator function of a nonempty closed convex set

$$\psi\left(x_1,\ldots,x_n\right)\stackrel{\text{def}}{=}\begin{cases}0, & \text{if } x_1=\cdots=x_n,\\ +\infty, & \text{otherwise.}\end{cases}$$

Generalization 1: Constrained Optimization

Consensus reformulation:
optimization in $\mathbb{R}^{nd}$

$$\min_{x_1,\ldots,x_n\in\mathbb{R}^d}\left\{\frac{1}{n}\sum_{i=1}^{n}f_i(x_i)+\psi(x_1,\ldots,x_n)\right\}$$

$$\psi(x_1,\ldots,x_n)\stackrel{\text{def}}{=}\begin{cases}0, & \text{if } x_1=\cdots=x_n,\\ +\infty, & \text{otherwise.}\end{cases}$$

Generalization 1

$$\psi(x_1,\ldots,x_n)\stackrel{\text{def}}{=}\begin{cases}0, & \text{if } (x_1,\cdots,x_n)\in C,\\ +\infty, & \text{otherwise.}\end{cases}$$

Arbitrary closed convex set (constraint)

Generalization 2: Composite Optimization

Consensus reformulation:

optimization in $\mathbb{R}^{nd}$

$$\min_{x_1,\ldots,x_n\in\mathbb{R}^d}\left\{\frac{1}{n}\sum_{i=1}^{n} f_i(x_i) + \psi(x_1,\ldots,x_n)\right\}$$

$$\psi(x_1,\ldots,x_n) \stackrel{\text{def}}{=} \begin{cases} 0, & \text{if } x_1=\cdots=x_n, \\ +\infty, & \text{otherwise.} \end{cases}$$

Generalization 2

$$\psi(x_1,\ldots,x_n) : \mathbb{R}^{nd} \to \mathbb{R}\cup\{+\infty\}$$

is a proper closed convex function

The epigraph of ψ is a closed and convex set

$$\text{epi}(\psi) \stackrel{\text{def}}{=} \{(x,t) \mid \psi(x) \le t)$$

Conceptual Simplification: from *nd* to *d'*

Composite optimization:

optimization in $\mathbb{R}^{nd}$

$$\min_{x_1,\ldots,x_n \in \mathbb{R}^d} \left\{ \frac{1}{n} \sum_{i=1}^{n} f_i\left(x_i\right) + \psi\left(x_1, \ldots, x_n\right) \right\}$$

Composite optimization:

optimization in $\mathbb{R}^{d'}$

$$\min_{x \in \mathbb{R}^{d'}} \{ f(x) + \psi(x) \}$$

$$\left\{ \begin{array}{c} d' = nd \\ x = (x_1, \ldots, x_n) \\ f(x) = \frac{1}{n} \sum_{i=1}^{n} f_i\left(x_i\right) \\ \psi(x) = \psi\left(x_1, \ldots, x_n\right) \end{array} \right\}$$

Part 3
Proximal Gradient Descent

Three Assumptions

The epigraph of ψ is a closed and convex set

$$\mathrm{epi}(\psi) \stackrel{\text{def}}{=} \{(x,t) \in \mathbb{R}^d \times \mathbb{R} \mid \psi(x) \le t)$$

$$\min_{x \in \mathbb{R}^d} f(x) + \psi(x)$$

A1 f is μ-convex and L-smooth:

$$\frac{\mu}{2}\|x-y\|^2 \le D_f(x,y) \le \frac{L}{2}\|x-y\|^2$$

Bregman divergence of f:

$$D_f(x,y) \stackrel{\text{def}}{=} f(x) - f(y) - \langle \nabla f(y), x-y \rangle$$

A2 $\psi : \mathbb{R}^d \to \mathbb{R} \cup \{+\infty\}$ is proper, closed, and convex

A3 ψ is proximable

The proximal operator $\mathrm{prox}_\psi : \mathbb{R}^d \to \mathbb{R}^d$ defined by

$$\mathrm{prox}_\psi(x) \stackrel{\text{def}}{=} \arg\min_{u \in \mathbb{R}^d} \left(\psi(u) + \frac{1}{2}\|u-x\|^2 \right)$$

can be evaluated exactly (e.g., in closed form)

Key Method: Proximal Gradient Descent

proximal operator:

$$\mathrm{prox}_{\psi}(x) \stackrel{\mathrm{def}}{=} \arg\min_{u \in \mathbb{R}^d} \left(\psi(u) + \frac{1}{2}\|u - x\|^2 \right)$$

stepsize

$$x_t - \gamma \nabla f(x_t)$$

gradient operator

$$x \mapsto x - \gamma \nabla f(x)$$

Proximal Gradient Descent: Theory

Theorem:

f is μ-convex and L-smooth:

$\frac{\mu}{2}\|x-y\|^2 \leq D_f(x,y) \leq \frac{L}{2}\|x-y\|^2$

$\frac{L}{\mu}$ is the condition number of f

$$t \geq \frac{L}{\mu}\log\frac{1}{\varepsilon} \quad \Longrightarrow \quad \|x_t - x_\star\|^2 \leq \varepsilon\|x_0 - x_\star\|^2$$

(for stepsize $\gamma = \frac{1}{L}$)

iterations

Error tolerance

$x_\star \overset{\text{def}}{=} \arg\min_{x\in\mathbb{R}^d} f(x) + \psi(x)$

Part 4
The ProxSkip Algorithm

What to do When the Prox is Expensive?

Can we somehow get away with fewer evaluations of the proximity operator in the Proximal GD method?

Approach 1

We'll skipp ALL prox evaluations!

The method is NOT implementable!

Serves as an inspiration for Approach 2

Approach 2 (ProxSkip)

We'll skip MANY prox evaluations!

The method is implementable!

Approach 1:
Simple, Extreme but Practically Useless Variant

Removing ψ via a Reformulation

$$h_\star \overset{\text{def}}{=} \nabla f(x_\star)$$

$$x_\star \overset{\text{def}}{=} \arg\min_{x \in \mathbb{R}^d} f(x) + \psi(x)$$

$$\min_{x \in \mathbb{R}^d} f(x) - \langle h_\star, x \rangle$$

$x_\star$ is a solution of the above problem!

By the 1st order optimality conditions, the solution satisfies $\nabla f(x) - \nabla f(x_\star) = 0$

We do not know $h_\star = \nabla f(x_\star)$!

Apply Gradient Descent to the Reformulation

$$h_\star \overset{\text{def}}{=} \nabla f(x_\star)$$
$$x_\star \overset{\text{def}}{=} \arg\min_{x \in \mathbb{R}^d} f(x) + \psi(x)$$

$$x_{t+1} = x_t - \gamma \left(\nabla f(x_t) - h_\star \right)$$

We do not need to evaluate the prox of ψ at all!

We do not know $h_\star$ and hence can't implement the method!

Idea: Try to "Learn" the Optimal Gradient Shift

Desire: $h_t \to h_\star$

$$x_{t+1} = x_t - \gamma \left(\nabla f(x_t) - h_t \right)$$

Perhaps we can learn $h_\star$ with only occasional access to ψ?

Approach 2:
The ProxSkip Method

ProxSkip: The Algorithm (Bird's Eye View)

1 $$\hat{x}_{t+1} = x_t - \gamma\left(\nabla f(x_t) - h_t\right)$$

2a with probability $1-p$ do ($1-p \approx 1$)

$$x_{t+1} = \hat{x}_{t+1} \qquad h_{t+1} = h_t$$

2b with probability p do ($p \approx 0$)

evaluate $\mathrm{prox}_{\frac{\gamma}{p}\psi}(?)$

$$x_{t+1} = ? \qquad h_{t+1} = ?$$

ProxSkip: The Algorithm (Detailed View)

Algorithm 1 ProxSkip

stepsize $\gamma > 0$, probability $p > 0$, initial iterate $x_0 \in \mathbb{R}^d$, initial control variate $h_0 \in \mathbb{R}^d$, number of iterations $T \geq 1$
for $t = 0, 1, \ldots, T-1$ **do**
  $\hat{x}_{t+1} = x_t - \gamma(\nabla f(x_t) - h_t)$ ◇ Take a gradient-type step adjusted via the control variate h_t
  Flip a coin $\theta_t \in \{0, 1\}$ where $\mathrm{Prob}(\theta_t = 1) = p$ ◇ Flip a coin that decides whether to skip the prox or not
  if $\theta_t = 1$ **then**
    $x_{t+1} = \mathrm{prox}_{\frac{\gamma}{p}\psi}\left(\hat{x}_{t+1} - \frac{\gamma}{p}h_t\right)$ ◇ Apply prox, but only very rarely! (with small probability p)
  else
    $x_{t+1} = \hat{x}_{t+1}$ ◇ Skip the prox!
  end if
  $h_{t+1} = h_t + \frac{p}{\gamma}(x_{t+1} - \hat{x}_{t+1})$ ◇ Update the control variate h_t
end for

Part 5
ProxSkip Theory

ProxSkip: Bounding the # of Iterations

Theorem:

f is μ-convex and L-smooth:
$\frac{\mu}{2}\|x-y\|^2 \leq D_f(x,y) \leq \frac{L}{2}\|x-y\|^2$
$\frac{L}{\mu}$ is the condition number of f

$$t \geq \max\left\{\frac{L}{\mu}, \frac{1}{p^2}\right\} \log\frac{1}{\varepsilon} \quad \Longrightarrow \quad \mathbb{E}\left[\Psi_t\right] \leq \varepsilon \Psi_0$$

t: # iterations

p = probability of evaluating the prox

Lyapunov function:

$$\Psi_t \stackrel{\text{def}}{=} \|x_t - x_\star\|^2 + \frac{1}{L^2 p^2}\|h_t - h_\star\|^2$$

ProxSkip: Optimal Prox-Evaluation Probability

Since in each iteration we evaluate the prox with probability p, the expected number of prox evaluations after t iterations is:

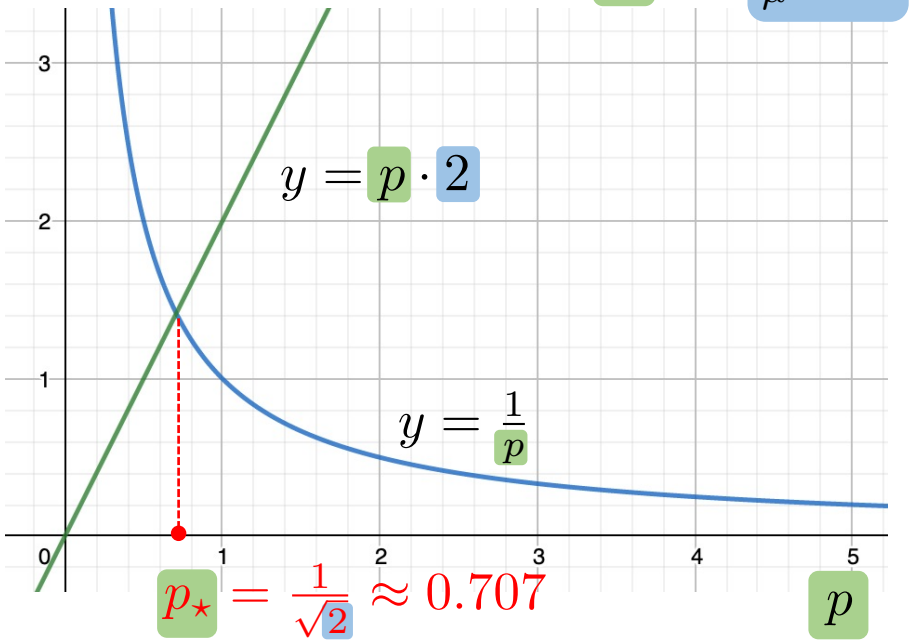
$\frac{L}{\mu}$ is the condition number of f

$$p \cdot t = p \cdot \max\left\{\frac{L}{\mu}, \frac{1}{p^2}\right\} \cdot \log\frac{1}{\varepsilon} = \max\left\{p \cdot \frac{L}{\mu}, \frac{1}{p}\right\} \cdot \log\frac{1}{\varepsilon}$$

Minimized for p satisfying $p \cdot \frac{L}{\mu} = \frac{1}{p}$

$$\Rightarrow \quad p_\star = \frac{1}{\sqrt{L/\mu}}$$

Computation of optimal $p_\star$ for $\frac{L}{\mu} = 2$



ProxSkip: # of Gradient and Prox Evaluations

$$p_\star = \frac{1}{\sqrt{L/\mu}} \quad \Rightarrow$$

# of iterations	$\max\left\{\frac{L}{\mu}, \frac{1}{p^2}\right\} \cdot \log\frac{1}{\varepsilon}$	$\frac{L}{\mu} \cdot \log\frac{1}{\varepsilon}$
# of gradient evaluations	$\max\left\{\frac{L}{\mu}, \frac{1}{p^2}\right\} \cdot \log\frac{1}{\varepsilon}$	$\frac{L}{\mu} \cdot \log\frac{1}{\varepsilon}$
Expected # of prox evaluations	$\max\left\{p \cdot \frac{L}{\mu}, \frac{1}{p}\right\} \cdot \log\frac{1}{\varepsilon}$	$\sqrt{\frac{L}{\mu}} \cdot \log\frac{1}{\varepsilon}$
Expected # of gradient evaluations between 2 prox evaluations	$\frac{1}{p}$	$\sqrt{\frac{L}{\mu}}$

Part 6
ProxSkip: Application to Consensus Reformulation of Federated Learning

Scaffnew [g] (this work) for any $p \in (0, 1]$	$\frac{1}{p}$ [h]	d	$\frac{1}{L}$	✓	$\tilde{\mathcal{O}}\left(p\kappa + \frac{1}{p}\right)$ [c]	✓ (for $p > \frac{1}{\kappa}$)
Scaffnew [g] (this work) for optimal $p = \frac{1}{\sqrt{\kappa}}$	$\sqrt{\kappa}$ [h]	d	$\frac{1}{L}$	✓	$\tilde{\mathcal{O}}(\sqrt{\kappa})$ [c]	✓

[a] This is a special case of S-Local-SVRG, which is a more general method presented in (Gorbunov et al., 2021). S-Local-GD arises as a special case when full gradient is computed on each client.

[b] FedLin is a variant with a fixed but different number of local steps for each client. Earlier method S-Local-GD has the same update but random loop length.

[c] The $\tilde{\mathcal{O}}$ notation hides logarithmic factors.

[d] G is the level of dissimilarity from the assumption $\frac{1}{n}\sum_{i=1}^{n} \|\nabla f_i(x)\|^2 \leq G^2 + 2LB^2\left(f(x) - f_\star\right), \forall x.$

[e] We use Scaffold's cumulative local-global stepsize $\eta_l \eta_g$ for a fair comparison.

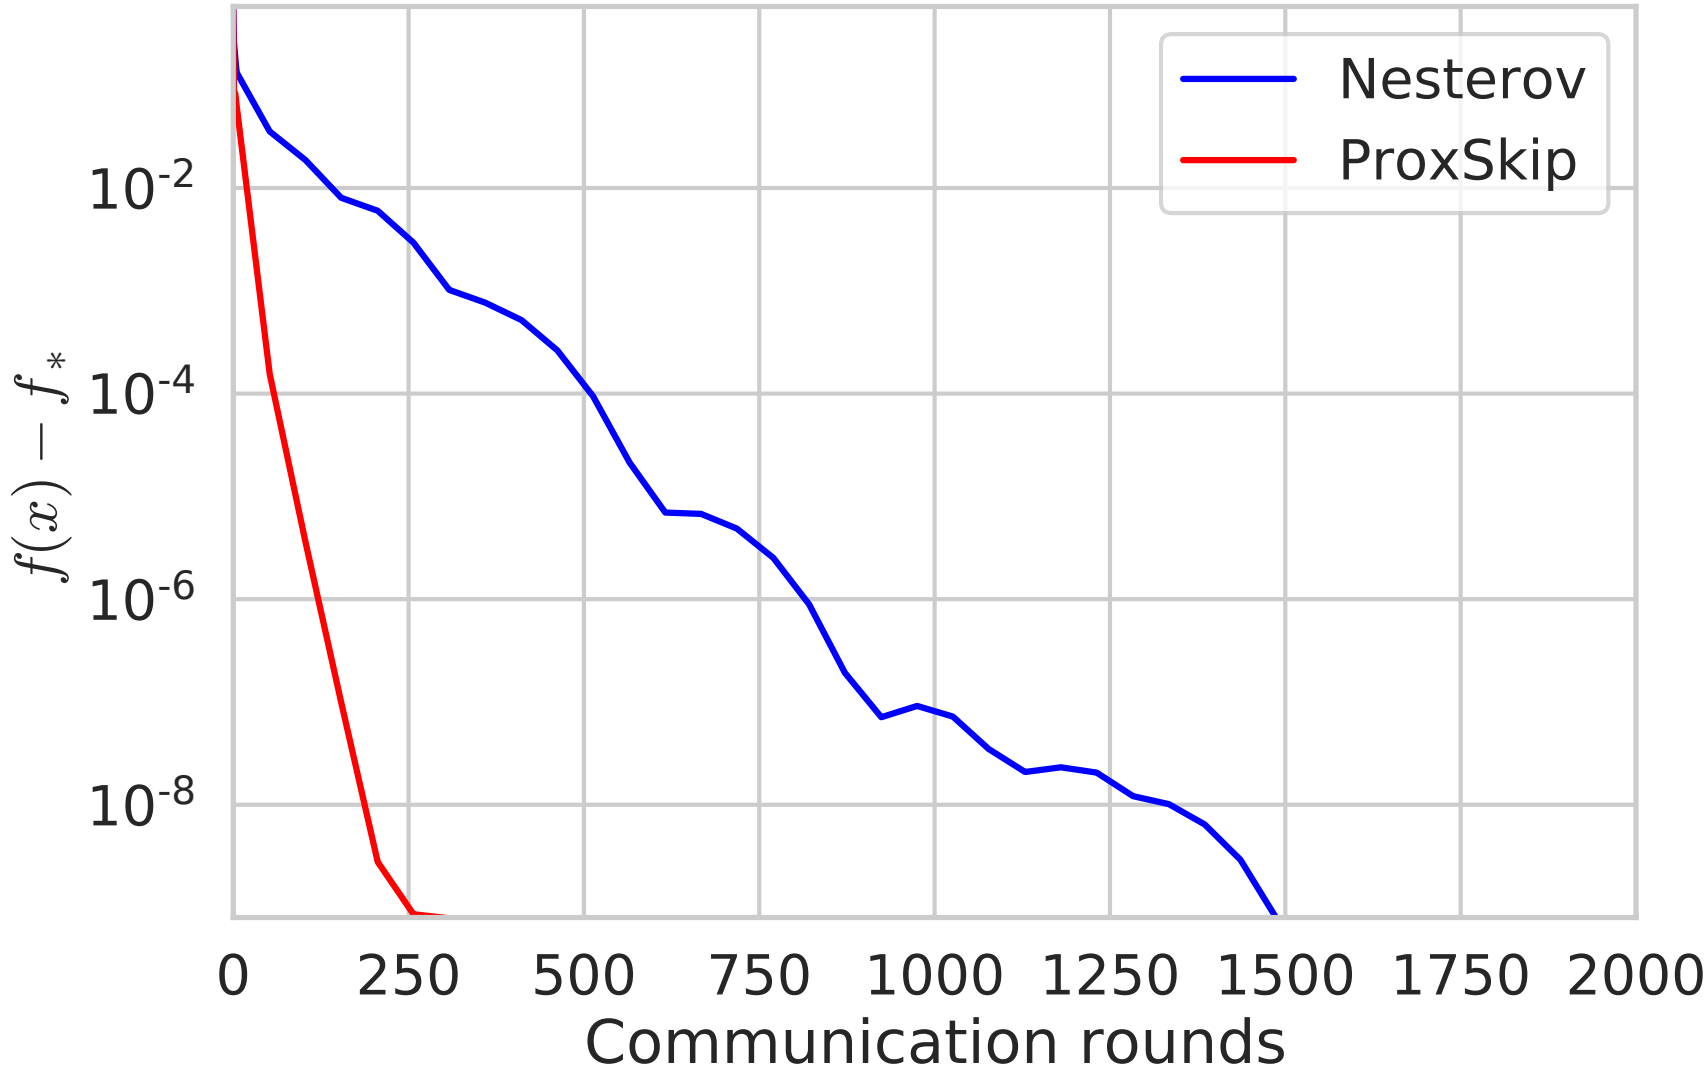
[f] The number of sent vectors depends on hyper-parameters, and it is randomized.

[g] Scaffnew (Algorithm 2) = ProxSkip (Algorithm 1) applied to the consensus formulation (6) + (7) of the finite-sum problem (5).

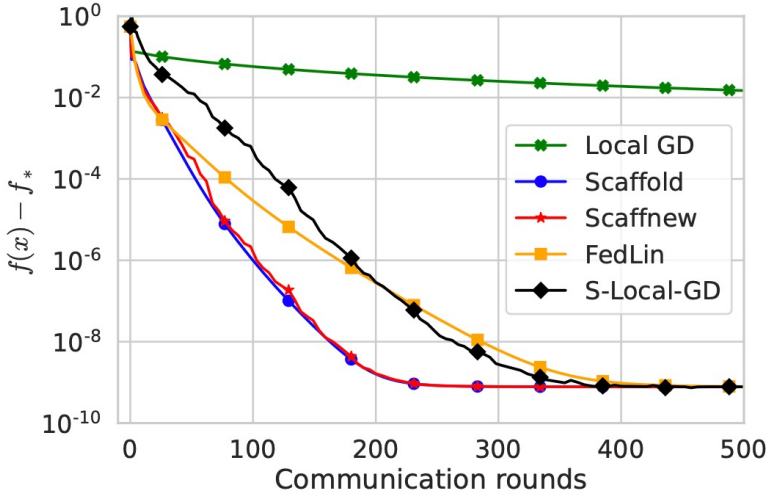
[h] ProxSkip (resp. Scaffnew) takes a *random* number of gradient (resp. local) steps before prox (resp. communication) is computed (resp. performed). What is shown in the table is the *expected* number of gradient (resp. local) steps.

Part 7
Experiments

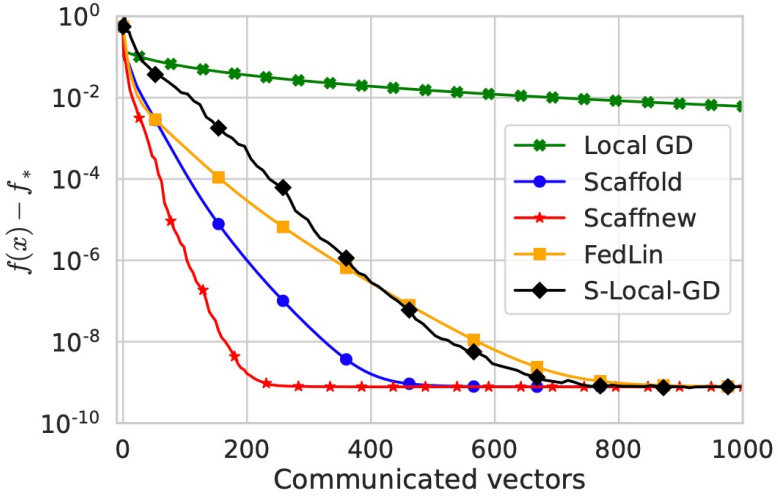
Scaffnew (=ProxSkip applied to FL) vs Nesterov



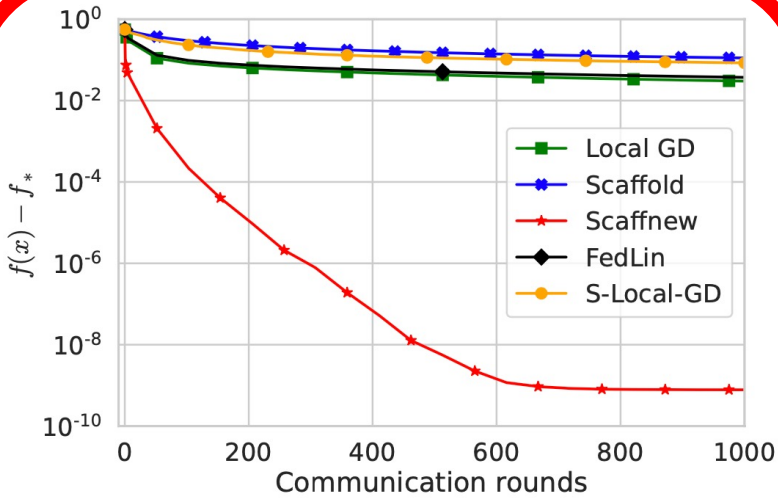
Scaffnew (=ProxSkip applied to FL) vs Baselines



(a) tuned hyper-parameters



(b) tuned hyper-parameters



(c) theoretical hyper-parameters

Figure 1. **Deterministic Problem**. Comparison of Scaffnew to other local update methods that tackle data-heterogeneity and to LocalGD. In (a) we compare communication rounds with optimally tuned hyper-parameters. In (b) we compare communicated vectors (Scaffold, FedLin and S-Local-GD require transmission of additional variables). In (c), we compare communication rounds with the algorithm parameters set to the best theoretical stepsizes used in the convergence proofs.

L2-regularized logistic regression:

$$f(x) = \frac{1}{n}\sum_{i=1}^{n} \log\left(1 + \exp\left(-b_i a_i^\top x\right)\right) + \frac{\lambda}{2}\|x\|^2$$

$$a_i \in \mathbb{R}^d,\ b_i \in \{-1, +1\},\ \lambda = L/10^4$$

Part 8
Extensions

Extension 1: From Gradients to Stochastic Gradients

- As described, in ProxSkip each worker computes the **full gradient** of its local function
- It's often better to consider a **cheap stochastic approximation of the gradient** instead
  - We consider this extension in the paper
  - We provide theoretical convergence rates

$$\nabla f_i(x_t) \quad \Rightarrow \quad g_i(x_t)$$

Full gradient — Stochastic gradient

Assumptions:

(unbiasedness) $\mathbb{E}\left[g_{i,t}(x_t) \mid x_t\right] = \nabla f_i(x_t)$

(expected smoothness) (Gower et al, 2019)
$$\mathrm{E}\left[\left\|g_{i,t}\left(x_t\right) - \nabla f\left(x_\star\right)\right\|^2 \mid x_t\right] \leq 2AD_f\left(x_t, x_\star\right) + C$$

Extension 2: From Fully Connected Network to Arbitrary Connected Network

- In each communication round of ProxSkip, **each worker sends messages to all oher workers** (e.g., through a server).
  - We can think of ProxSkip workers as the nodes of a **fully-connected network.**
  - In each communication round, all **workers communicate with their neighbors.**
- In the paper we provide extension to **arbitrary connected networks.**
